Why bother?

 Economists and academics are bad at many things. One of them is graphics.

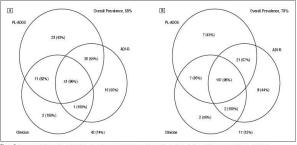

Figure 2. Frequency of diagnostic combinations at age 2 years and prevalence of best-estimate diagnosis (in parentheses) at age 9 years. A, Autism. 8. Autism spectrum, Pt-ADOS indicates Pre-Linguistic Autism Diagnostic Observation Schedule; ADI-R, Autism Diagnostic Interview-Revised.

- But they are good at two things that journalists can learn.
 - Causal inference.
 - Quantifying uncertainty.
- Why should you care?
 - Dissect studies.
 - Talk to academics in their language.
 - Use econometric tools in your own reporting.

- The standard tool of econometrics is the ordinary least-squares (linear) regression. It's useful and well-understood.
 - But it's easy to abuse to find spurious correlations.¹
 - Also, it's a little boring.

http://www.tylervigen.com/spurious-correlations

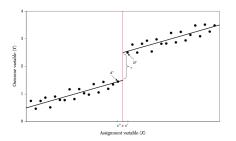

- Today, we'll run through three other techniques in applied econometrics.
 - This will be focused on examples. It will not be focused on theory or on coding.
 - In other words, it's going to be abstract, but not too abstract.

Regression discontinuity

- Like economists, we're often after causality. It's more interesting to say that X causes Y, not merely that X and Y are related.
- The gold standard: randomized trials.
 - Think military drafts. Because whether you're drafted is essentially random, we can use the difference in outcomes between the two groups to analyze the causal effect of joining the military.
- Often in real life, we don't have that kind of randomness.²
- So, we take some sort of cutoff, and assume that if you're close to the cutoff, which side you're on is basically random.

 $^{^2}$ For example, we can't randomly give aid to some poor nations but not others.

- Here's the classic example.³
 - Say that if you get a 2000 or above on your SAT, you're guaranteed to get into college, but if you get below a 2000, you don't.
 - The difference in ability between someone who gets a 1980 and a 2020 is basically nothing.
 - So we can use the difference in the earnings of people who got below a 2000 and above a 2000 to get the causal effect of college admission on earnings.

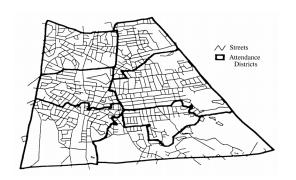

³More examples can be found in [Lee and Lemieux, 2010], pp. 339-42.

- Discontinuities due to policy or custom.⁴
 - The maximum number of students per teacher in Israel is 40.
 - But a cohort with 40 students is basically the same as a cohort of 41 students except for how many teachers they have.
 - This can be used to get the causal effect of classroom size on test scores

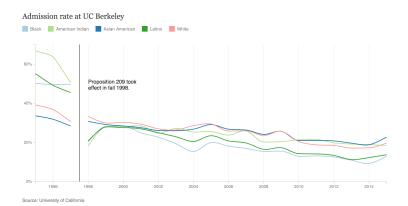

⁴See [Angrist and Lavy, 1999].

- Geographic distance from a border where some meaningful policy change happens.⁵
 - Consider houses on two sides of a school district border. They are basically the same except for the school they're assigned to.
 - With data on home prices, this can be used to figure out how much parents are willing to pay to send their children to better schools.

⁵See [Black, 1999].

- How to do it
 - Draw a scatterplot, then draw two trend lines on either side of the cutoff.
 - The visual discontinuity can be powerful even without the underlying statistics, but make sure the effect you observe is significant.

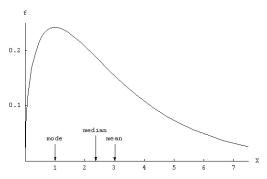

- Run a linear regression with a binary variable to indicate the side of the cutoff you're on. Then check the magnitude and significance of the coefficient.
 - Python: statsmodels.OLS.
 - See github.com/natematias/research_in_python for an example in a Jupyter notebook.

	coef	std err	t	P> t	[95.0% Cont	f. Int.]	
Intercept	70.1188	1.151	60.908	0.000	67.856	72.382	
csize	-0.1392	0.119	-1.168	0.243	-0.373	0.095	
small	3.9531	1.800	2.197	0.029	0.416	7.491	

Quantile regression

- Ordinary least-squares estimates the conditional mean of a dependent variable given particular values of the independent variables.
- But for skewed distributions, the mean can be misleading.
 Sometimes the median is more informative.
- What if we could estimate the conditional median of a function? Or the 25th percentile, or the 99th percentile...

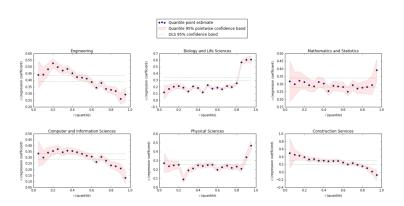

- Example: I want to know what to major in to boost my future earnings.
- First attempt: Average earnings by major.
 - But men earn more on average, and engineering majors are more likely to be male.

	INCWAGE
DEGFIELD	
Engineering	111888.19
Biology and Life Sciences	104841.85
Physical Sciences	102970.25
Mathematics and Statistics	100254.41
Computer and Information Sciences	95371.24
Social Sciences	95007.78
Transportation Sciences and Technologies	91478.05
Business	89170.16
Construction Services	88169.26
Engineering Technologies	87997.63

- Second attempt: Linear regression to account for gender, race and age.
 - Engineering Technologies drops out of the list because it is skewed male.
 - Biology still appears second on the list.
 - Doctors make a lot of money, but many biology majors end up as medical technicians.
 - Maybe we want to look at the median earnings. Or better yet, maybe we want a fuller picture of the distribution of earnings.

- Third attempt: Quantile regression. What is the effect on earnings at some quantile of majoring in X (relative to some reference major), controlling for race, gender and age?
 - Earnings at the 95th percentile for biology majors look very different than the median.

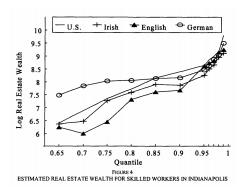

- Effect of mother's race on birthweight.⁶
 - At the lowest quantiles, babies born to black mothers weigh 300 g less than those born to white mothers. At the top quantiles, the difference is more like 150 g.

⁶See [Koenker and Hallock, 2001].

- Ethnicity and wealth across 19th-century American cities.⁷
 - At the lowest quantiles, German workers in Indianapolis are far wealthier than others. At the top quantiles, this effect disappears.

⁷See [Conley and Galenson, 1998].

- How to do it
 - Pretty much like an OLS regression computed for a given quantile.
 - Works by dividing your sample into "cells" for each combination of the explanatory variables, so it requires a large sample size.⁸
 - Python: statsmodels.quantReg.
 - See me for the college majors example in a Jupyter notebook.

⁸Sort of.

Survival analysis
